Database Project Information

## DC/Marvel Superhero Outline

Our database is a miniworld that tries to represent the different heroes and villains in the DC Universe. It has been designed to be used by anyone looking for some information on their favorite hero or villain. It is made up of Characters, Cities, Super Powers, and Teams. Even though there are only four entities, it can provide some interesting data, such as who antagonizes who, the number of villains and heroes in a given city, or even which characters share the same super powers. While a database of super heroes and villains doesn't really have an application in the real world (sure there are heroes and villains, but none are truly super), it does demonstrate an ability to track different types of people with different attributes across multiple cities and if there are any conflicts or alliances between them.

## DC/Marvel Superhero Database Outline

Our database consists of four different entities and five different relationships between the entities. Our entities are Characters, City, SuperPowers, and Teams. They relate to each other by means of Leadership, Antagonists, SuperPowerDetails, CityDetails, and TeamAffiliations.

### Characters:

The characters table is probably the most interesting table in the database, as it contains most of the text information for the heroes and villains. While there are quite a few columns for this table, there are only a handful of mandatory columns: alias, superpower\_1 and 2, team, and city. The primary key for the table is its id, and its foreign keys are both superpowers (which reference the superPowers table by superpower id), team (references team table by team id) and city (references the city table by city id).

### City:

The city table is populated with information that can be pulled to fill in portions of the character's table. It contains details on the cities name, hero population, and villain population. Aside from its id, the only other mandatory field is the city name, as it is possible to have a city without any heroes or villains, but it is not possible to have a city without a name.

#### SuperPowers:

This is another interesting table. It contains all of the different super powers' names, the type of power (physical or mental), and a description of the power. Every single field of this table is mandatory, as it is not possible to have an unnamed power or a power without a type or description.

#### Teams:

This table stores the information for a few of the DC universes' character teams. It only has one mandatory field, team\_name, as it is possible to have a team that doesn't have any heroes or villains in it, but it is not possible to have a team of heroes without a team name.

#### Leadership (One to Many relationship):

This represents the one-to-many relationship a hero or villain can have to its subordinates. One hero can be the leader of none to many heroes, and the same goes for villains. It lets the user see who is in charge of who. However, seeing as many of these characters are strong willed individuals, do not be surprised if they answer to no one.

#### Antagonists (Many to Many relationship):

This represents the many-to-many relationship between heroes and villains. A hero can have many villain antagonists, and a villain can have many hero antagonists. However, do not be surprised if many of the villains in this database have the same antagonist.

#### SuperPowerDetails (Many to Many relationship):

This represents the many-to-many relationship between characters and superpowers. Superpowers are not restricted to one individual character, in fact, it is not uncommon for many characters to have some degree of the same power.

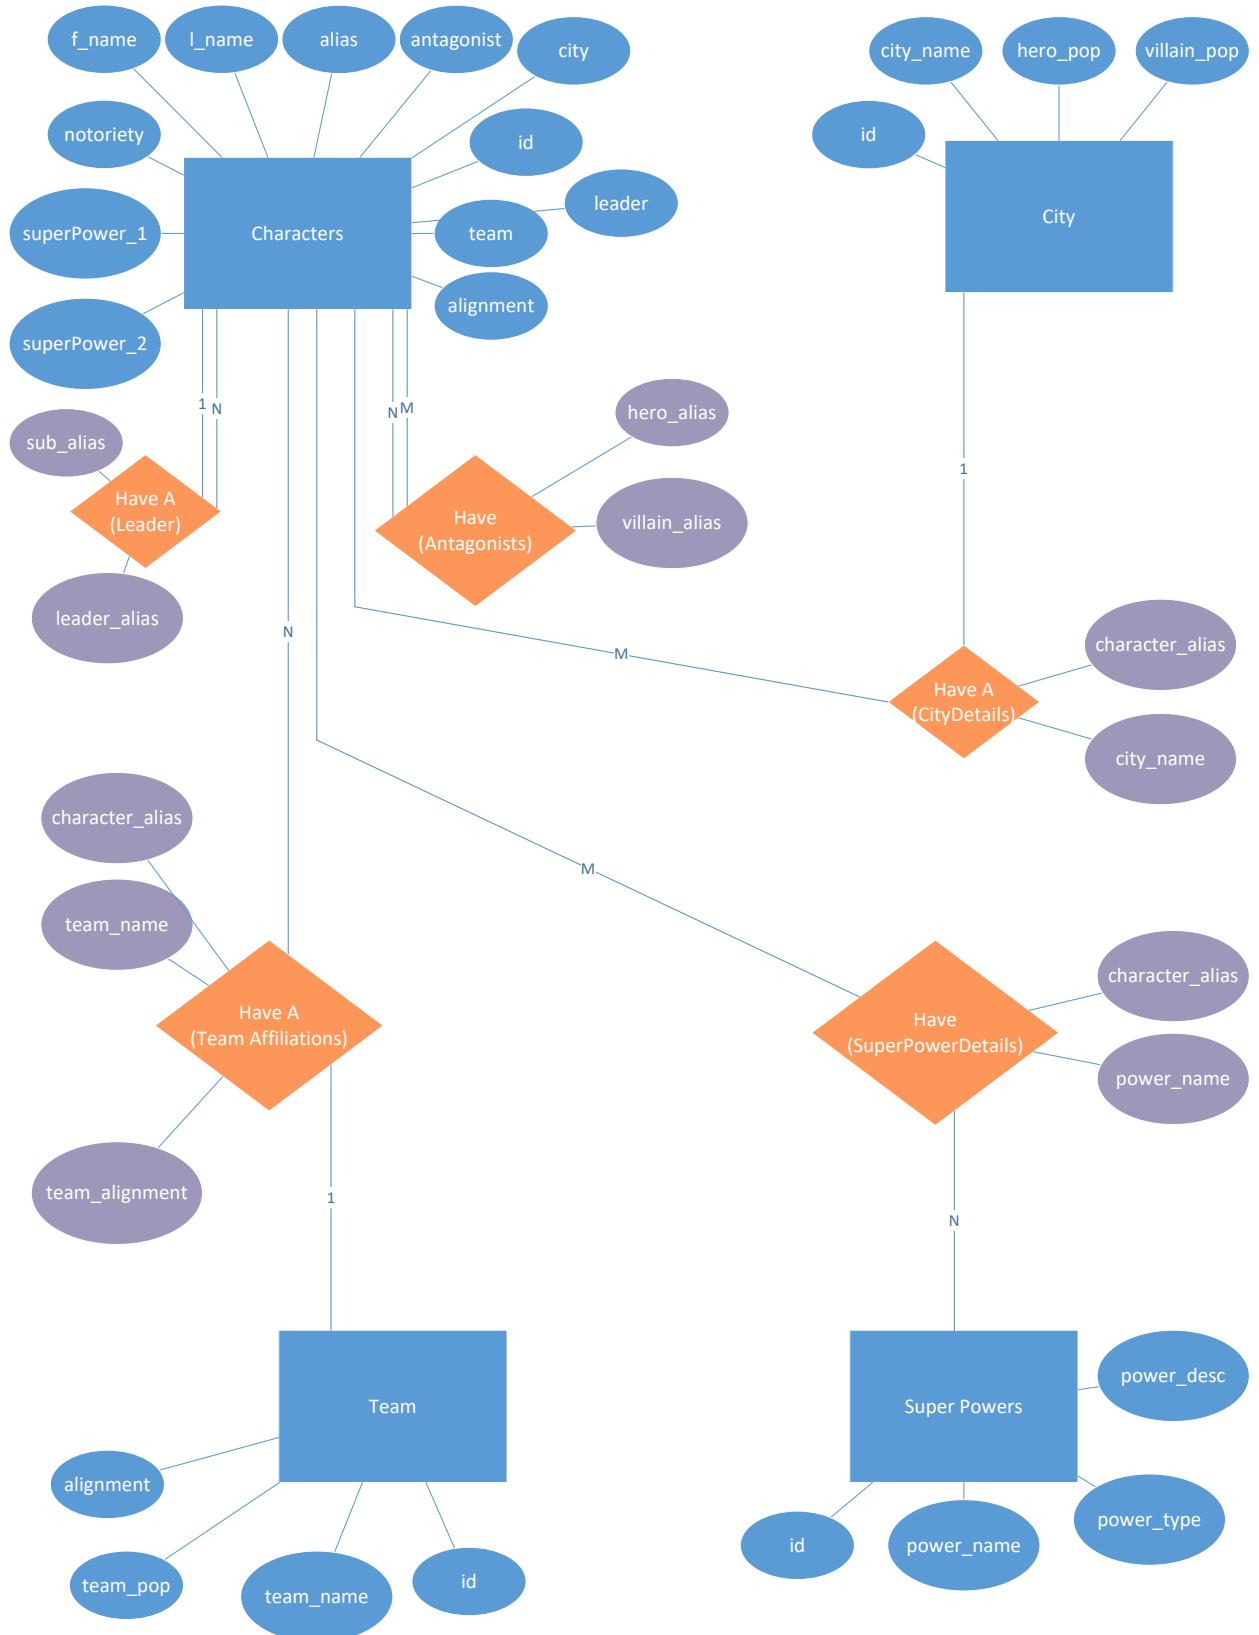

#### CityDetails (One to Many relationship):

This represents the relationship between characters and their main city. A city can have many characters reside in it, but only one character can have a city that they're from.

#### TeamAffiliations (One to Many relationship):

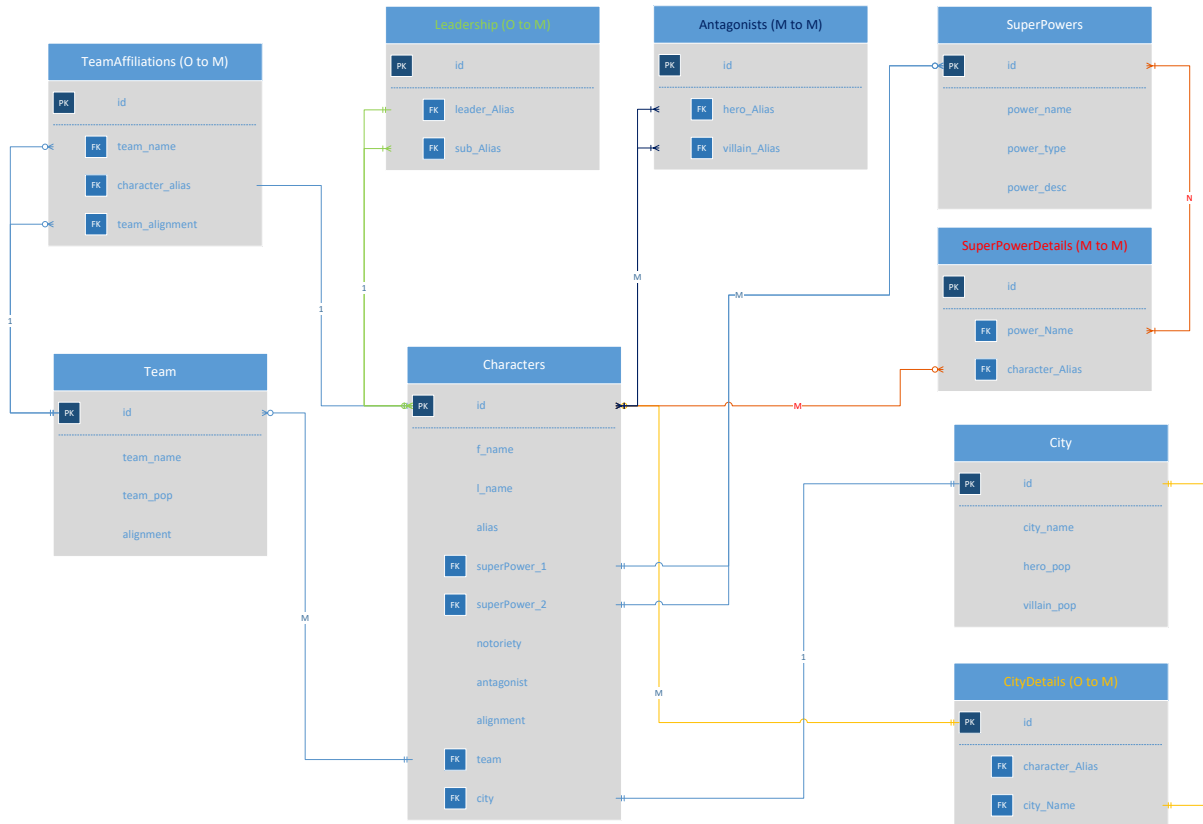

As with the character's relationship to cities, their relationship to teams is the same. A team can have many characters, but a character can only belong to one team at a time.

# DC/Marvel Superhero Database ER Diagram

note: id is the primary key for all entities. When pdf-ing the diagram, the underline was lost for some unknown reason.
